v1.1

- 1 Introduction
- 2 Block Cipher Modes of Operation
- 3 Block Cipher Construction

# Pleased to meet you...

## Who am I, anyway?

- ▶ Ph.D. candidate.
  - Area: Algorithmic Algebraic Number Theory
  - Advisor: Daqing Wan
- ▶ B.S. Computer Science (Cal Poly, San Luis Obispo)
- ▶ Worked at an information security consulting firm for 10 years.
  - I evaluated security products against various government standards.
  - I've looked at many, many products.

# The Story Thus Far

A block cipher is a family of bijective functions, indexed by the key  $k \in \mathcal{K}$ . We call these families “encrypt” ( $e_k$ ) and “decrypt” ( $d_k$ ):

$$e_k : \mathcal{M} \rightarrow \mathcal{C}$$

$$d_k : \mathcal{C} \rightarrow \mathcal{M}$$

- ▶ For block ciphers,  $\mathcal{M}$  and  $\mathcal{C}$  are the same set.
- ▶ Every element of these sets are  $b$ -bit (binary) strings for some fixed  $b$ .
- ▶ This length,  $b$ , is called the **block size**.

We will discuss:

- ▶ A variety of common and (sometimes) reasonable-to-use block cipher modes of use (this class and next).
- ▶ Some explicit examples of block cipher construction (starting November 14, 2012):
  - DES
  - AES

# Block Cipher Modes of Use Outline

## 1 Introduction

## 2 Block Cipher Modes of Operation

- Block oriented Confidentiality Modes
- Stream-cipher-like Confidentiality Modes
- Data Integrity Modes
- Combined Confidentiality / Integrity Modes
- Block Cipher Modes of Operation Conclusion

## 3 Block Cipher Construction

# Block Cipher Modes Travel Guide

We'll discuss a few of the more common and useful modes of use:

- ▶ Block oriented Confidentiality Modes:
  - ECB
  - CBC
- ▶ Stream-cipher-like Confidentiality Modes
  - OFB
  - CTR
- ▶ Data Integrity Modes
  - CBC-MAC
  - CMAC
- ▶ Combined Confidentiality / Integrity Modes
  - CCM

## Subsection 1

# Block oriented Confidentiality Modes

- ▶ The basic cipher, without modification.
- ▶ Split the plaintext into blocks, and encrypt each block independently.

- ▶ No inter-dependency between blocks.
- ▶ Bit errors render the rest of the block uncontrollably corrupted.
- ▶ Encryption of identical plaintext blocks under the same key yield identical ciphertext blocks.
  - Exposes plaintext structural information.
  - Susceptible to attacker blockwise modification.

- ▶ I am a member of the MAA
- ▶ In Nomathistan, being a member of the MAA is punishable by death.
- ▶ When traveling, I thus must encrypt my pro-math propaganda:

**Math  
is  
Great!!!**

# ECB: A Dungeon Dispatch

- ▶ I am a member of the MAA
- ▶ In Nomathistan, being a member of the MAA is punishable by death.
- ▶ When traveling, I thus must encrypt my pro-math propaganda:

**Math  
is  
Great!!!**

DES ECB  
→

# ECB: A Dungeon Dispatch

- ▶ I am a member of the MAA
- ▶ In Nomathistan, being a member of the MAA is punishable by death.
- ▶ When traveling, I thus must encrypt my pro-math propaganda:

**Math  
is  
Great!!!**

DES ECB  
→

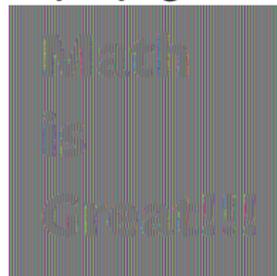

# ECB: A Dungeon Dispatch

- ▶ I am a member of the MAA
- ▶ In Nomathistan, being a member of the MAA is punishable by death.
- ▶ When traveling, I thus must encrypt my pro-math propaganda:

**Math  
is  
Great!!!**

DES ECB

- ▶ Structural information is exposed to an adversary.

# ECB: Message Order Matters!

- ▶ Blocks can be reordered.
- ▶ Reordering or repetition of blocks can change the message.
- ▶ Any ciphertext encrypted with the same key can be used as source material for the attacker.
- ▶ ECB security is dependent on the plaintext data formatting!

- ▶ Uses a 1-block initial vector (IV)
- ▶ IV is XORed with plaintext before encryption
- ▶ For later blocks, uses the prior ciphertext as the IV

# CBC Diagram

Source: NIST SP800-38A

- ▶ Encrypting the same plaintext under the same key produces different ciphertext, so long as the block IV is different
  - Different IV choice
  - Different prior plaintext
  - In the instance of IV collision, structural information is revealed (as with ECB).
- ▶ IV must be unpredictable (but need not be secret) but IV integrity should be assured.
- ▶ No error should be issued if padding is invalid. (*n.b.* Vaundenay, 2002)
- ▶ In the event of an error:
  - Block associated with change is fully corrupted.
  - Next block has changes to plaintext that are the error XOR the original plaintext.
  - Future blocks uncorrupted.

# CBC: The Rosencrantz & Guildenstern Affair

# The Birthday Paradox, Writ Large

- ▶ We model most cryptographic primitives as random mappings.
- ▶ For many of our uses, it is interesting when a new output is equal to an old output; this is called a **collision**.
- ▶ What is the probability that some output is equal to a prior output after  $j$  outputs have been produced?
- ▶ Probability of “no collision” is easier to address, and then take the complement. After  $j$  outputs:

$$\begin{aligned}\Pr(\text{collision}) &= 1 - \prod_{k=0}^{j-1} \left(1 - \frac{k}{2^b}\right) \\ &= 1 - \frac{(2^b)(2^b - 1)(2^b - 2) \cdots (2^b - j + 1)}{2^{bj}} \\ &= 1 - \frac{(2^b)^j}{2^{bj}}\end{aligned}$$

# Let's ask Newton

- ▶ Recall  $e^x = \sum_{k=0}^{\infty} \frac{x^k}{k!}$ ; so long as  $x$  is close to 0,  $e^x \approx 1 + x$ .
- ▶ The terms in our product look like  $1 - \frac{k}{2^b}$ .
- ▶ To approximate we set  $1 - \frac{k}{2^b} = 1 + x$  and find that  $x = -\frac{k}{2^b}$ .
- ▶ This yields the approximation:

$$\Pr(\text{collision}) \approx 1 - \prod_{k=0}^{j-1} e^{k/2^b} = 1 - \exp\left(-\frac{j(j-1)}{2^{b+1}}\right)$$

- ▶ So long as  $j \ll 2^b$ , this approximation remains quite reasonable.

# How Much Wood...

| Block Size | Pr(collision) |           |          |
|------------|---------------|-----------|----------|
|            | $2^{-40}$     | $2^{-20}$ | $2^{-1}$ |
| 64         | $2^{11}$      | $2^{21}$  | $2^{31}$ |
| 128        | $2^{43}$      | $2^{53}$  | $2^{63}$ |

Table : Allowed Outputs for Target Collision Probability

## Subsection 2

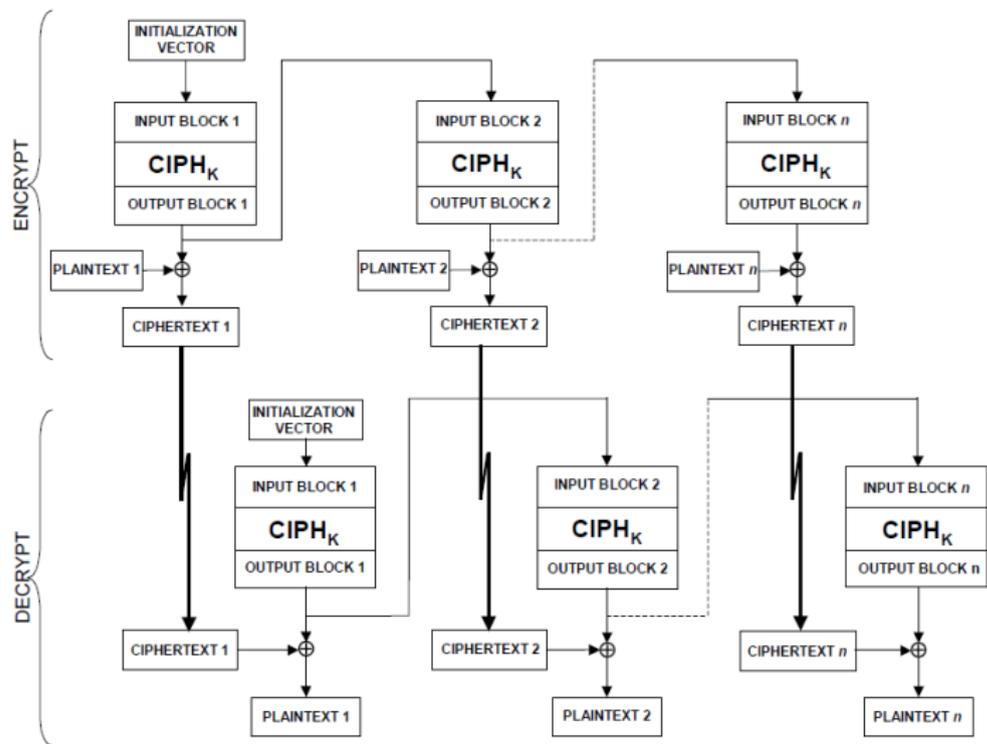

# Stream-cipher-like Confidentiality Modes

- ▶ A stream cipher mode that can encrypt arbitrary blocks of data (though specified to work 1 block at a time)
- ▶ IV is the initial cipher input.
- ▶ Output of cipher is the keystream, and is XORed with the plaintext to create the ciphertext.
- ▶ Prior keystream becomes the next IV

# OFB Diagram

Source: NIST SP800-38A

- ▶ Uses cipher in encrypt mode only
- ▶ Keystream is in no way affected by the plaintext
- ▶ Anytime there is an IV collision under the same key, the produced keystream is the same.
- ▶ In the instance of (Key,IV) collision, *all future* plaintexts are revealed, and the corresponding past plaintexts.
- ▶ IV must be a nonce, that is, it must only occur once per key.
- ▶ In the event of an error:
  - Bitwise equivalent changes occur in the corresponding plaintext.
  - Blocks after the altered block are unaffected.
  - An attacker can perform bit-level targeted modification to the plaintext.

# Cycles Within Cycles

- ▶ There is absolutely no external input into the keystream generation process after initialization.
- ▶ Once a keystream block repeats, the keystream generation is trapped in a cycle, and cannot recover.
- ▶ If the attacker XORs two blocks of ciphertext that used the same keystream, the result is two plaintexts XORed (this is considered decrypted).
- ▶ Cycle detection isn't cheap or fast (and is thus not commonly done).
- ▶ How many blocks should be encrypted with a single key?

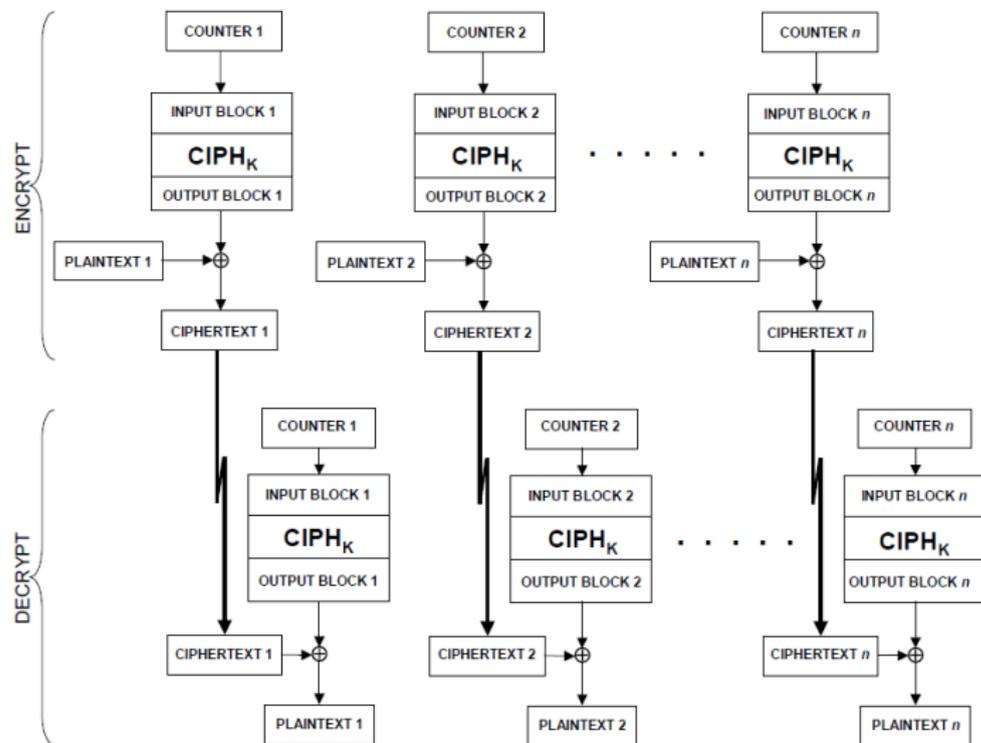

| Block Size | Pr(collision) |           |          |
|------------|---------------|-----------|----------|
|            | $2^{-40}$     | $2^{-20}$ | $2^{-1}$ |
| 64         | $2^{11}$      | $2^{21}$  | $2^{31}$ |
| 128        | $2^{43}$      | $2^{53}$  | $2^{63}$ |

- ▶ A stream cipher mode that can encrypt arbitrary blocks of data (though specified to work 1 block at a time)
- ▶ Intended as a safer and more predictable version of OFB mode.
  - Instead of using prior keystream as the next cipher input, uses a counter.
  - The counter increments in some defined way.
  - The counter can not be allowed to repeat under the same key.
- ▶ Output of cipher is the keystream, and is XORed with the plaintext to create the ciphertext.

# CTR Diagram

Source: NIST SP800-38A

- ▶ Uses cipher in encrypt mode only
- ▶ Keystream is in no way affected by the plaintext
- ▶ Anytime there is a counter collision under the same key, the produced keystream is the same.
- ▶ In the instance of (Key,Counter) collision, *all future* plaintexts are revealed, and the corresponding past plaintexts.
- ▶ In the event of an error:
  - Bitwise equivalent changes occur in the corresponding plaintext.
  - Blocks after the altered block are unaffected.
  - An attacker can perform bit-level targeted modification to the plaintext.

# Stream Ciphers: The Rosencrantz & Guildenstern Affair

- ▶ XOR desired message with plaintext message.
- ▶ XOR the result with the ciphertext.
- ▶ Decryption is now the desired message.

## Subsection 3

# Data Integrity Modes

- ▶ An integrity mode, based on the CBC encryption mode.
- ▶ Set the IV to all 0s.
- ▶ Encrypt the data to be protected, and discard all ciphertext other than the last block.
- ▶ Optionally truncate this block of ciphertext.
- ▶ Send the data (possibly separately encrypted) and the CBC-MAC.

- ▶ If the plaintext to be authenticated is not block aligned, the last block must be padded.
- ▶ There is message ambiguity unless this padding is unambiguous.
- ▶ CBC-MAC keys should be different than encryption keys (particularly when used for CBC encrypt mode!)
- ▶ Security in the case of fixed length messages, or messages that include the message length in the first block, is excellent.
- ▶ Other uses (no length specified, or the length in the last block) suffer from extension attacks.

# A Note on Message Padding

- ▶ Some naïve padding schemes can lead to message ambiguity.
  - The MAC of a message that was padded and a message whose end happens to resemble padding should not be the same.
  - Simply appending all 0s or all 1s is ambiguous. Where does the message end?
  - One common system is appending a binary 1 followed by as many 0s as necessary
- ▶ For CBC-MAC, to prevent message ambiguity, one must do at least one of the following:
  - Force all messages to be same fixed length.
  - Prepend the message length (and reject messages of the incorrect length).
  - Always unambiguously pad, even for messages that are block aligned (*n.b.* block aligned messages have a full block of padding added).

# An Example of the CBC-MAC Extension Attack

- ▶ The attacker can query a CBC-MAC oracle which operates using key  $k$ .
- ▶ The attacker requests the CBC-MAC of a one block message,  $m$ , from the oracle and obtains  $t_1$ .
- ▶ The attacker requests the CBC-MAC of the message  $t_1$  from the oracle, obtaining  $t_2$ .
- ▶ The attacker then knows the CBC-MAC of the two block message  $(m||0)$ , namely  $t_2$  (where  $||$  denotes string concatenation.)

# A More General CBC-MAC Extension Attack

- ▶ The attacker requests the CBC-MAC of the messages  $m$  and  $m'$ , obtaining  $t$  and  $t'$ , respectively.
- ▶ Denote the blocks making up  $m'$  as  $m' = m'_1 || \dots || m'_n$ .
- ▶ The attacker then knows the MAC for a derived message,  $m || (m'_1 \oplus t) || m'_2 || \dots || m'_n$ , namely  $t'$ .

# CBC-MAC and CBC Mode: Why Distinct Keys?

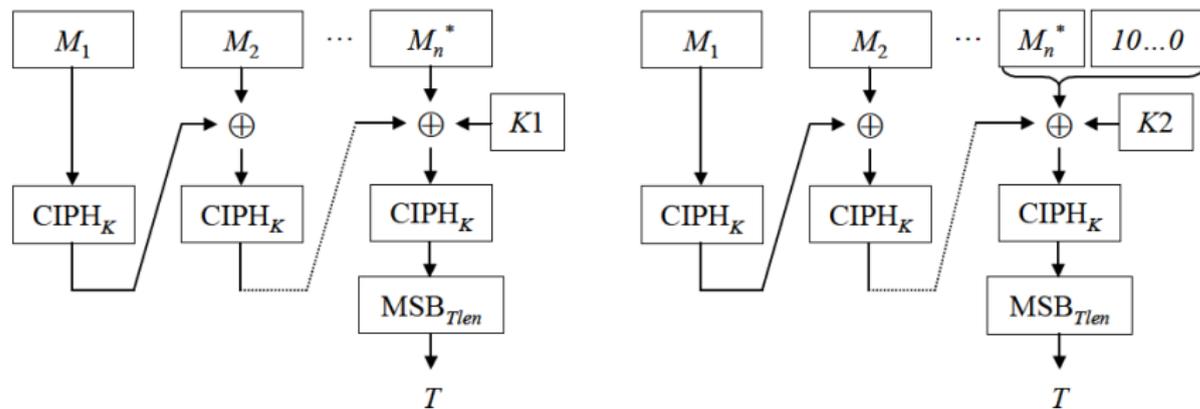

- ▶ As a general principle of cryptographic hygiene, keys should be used for only a single type of use:
  - A single mode of use
  - A single class of data (e.g., keys used to protect key management data should be different than keys used to protect user data.)
- ▶ Using the same key for both CBC-MAC and CBC encryption is useless.
  - So long as the attacker does not modify the final block of ciphertext, the CBC-MAC of the decrypted message will remain constant.

- ▶ A modern integrity mode, based on Phillip Rogaway's OMAC1
- ▶ Does not suffer from extension attacks
- ▶ Does not require encoding the length in the data, or a fixed data length.
- ▶ Pads partial last blocks unambiguously
- ▶ Uses one of two different subkeys,  $K_1$  and  $K_2$ , for the final block, depending on the length of the last block.
  - Subkeys are derived by encrypting a block of 0s under  $K$  (+ some other processing).
- ▶ Allows truncating the resulting MAC output to 64 bits or longer.

# CMAC Diagram

Source: NIST SP800-38B

## Subsection 4

# Combined Confidentiality / Integrity Modes

- ▶ Provides data integrity (via CBC-MAC)
  - CBC-MAC is applied to the plaintext data.
  - Data length is prepended to data stream.
  - There is a provision for some data to be authenticated but not encrypted.
- ▶ Provides confidentiality (via CTR mode)
  - MAC is encrypted

## Subsection 5

# Block Cipher Modes of Operation Conclusion

# What Did You Learn in School Today?

- ▶ Even idealized block ciphers are not magical.
- ▶ Some cipher modes are brittle.
- ▶ Most block cipher modes allow the attacker to make some targeted changes to the decrypted plaintext.
- ▶ Stream-cipher-like modes allow the attacker to make any desired changes to the decrypted plaintext.
- ▶ Detection of noise or attacker-induced corruption should not be dependent on message structure.
- ▶ Any confidentiality mode should be used in conjunction with some reasonable data integrity scheme.
- ▶ There are some modes that provide data integrity/authenticity.
- ▶ There are some modes that provide both confidentiality and data integrity/authenticity.

# Block Cipher Example Outline

- 1 Introduction
- 2 Block Cipher Modes of Operation
- 3 Block Cipher Construction**
  - DES
  - AES
  - DES/AES Conclusion

# General Approaches

- ▶ Substitution
- ▶ Permutation
- ▶ Expansion
- ▶ Compression (de-expansion)
- ▶ “Math”
- ▶ Integration of Keying Material

One can (and should) combine these approaches. This is called a **product cipher**.

## Subsection 1

DES

# DES: History

- ▶ IBM designed several variants of a cipher called Lucifer.
- ▶ One of these variants (Feistel network, 64 bit block size, 64 bit key) was submitted to the National Bureau of Standards (NBS).
- ▶ The NSA worked with IBM to tune the algorithm:
  1. Reduced the key size to 56 bits.
  2. Changed the S-Boxes.
  
- ▶ DES was adopted in by the NBS in FIPS 46 in 1977, and then renewed as a standard in 1983, 1988, 1993, and 1999. FIPS 46-3 was withdrawn in 2005.
- ▶ The NSA changes were controversial, and many suspected that the NSA weakened the design.
- ▶ This induced (or was coincident with) the rise of an academic cryptologic research community.

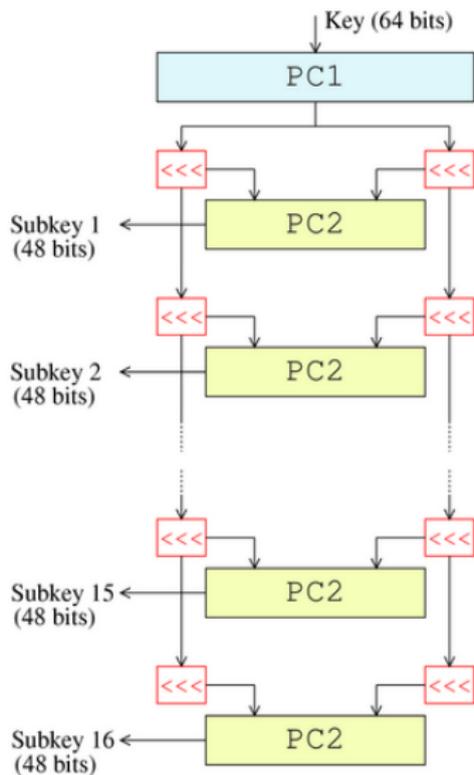

- ▶ IBM designed several variants of a cipher called Lucifer.
- ▶ One of these variants (Feistel network, 64 bit block size, 64 bit key) was submitted to the National Bureau of Standards (NBS).
- ▶ The NSA worked with IBM to tune the algorithm:
  1. Reduced the key size to 56 bits.
  2. ~~Changed the S-Boxes.~~
  3. Don Coppersmith revealed that IBM developed the S-Boxes (and knew about differential cryptanalysis).
- ▶ DES was adopted in by the NBS in FIPS 46 in 1977, and then renewed as a standard in 1983, 1988, 1993, and 1999. FIPS 46-3 was withdrawn in 2005.
- ▶ The NSA changes were controversial, and many suspected that the NSA weakened the design.
- ▶ This induced (or was coincident with) the rise of an academic cryptologic research community.

- ▶ 64 bit block size.
- ▶ 56 bit key (in a 64 bit block; LSB of each byte is optionally a parity bit to force odd parity).
- ▶ Cipher consists of a few distinct components:
  - Key Scheduler (establishes encrypt or decrypt)
  - The Initial Permutation (and its corresponding inverse, the Final Permutation)
  - Feistel network (16 rounds).

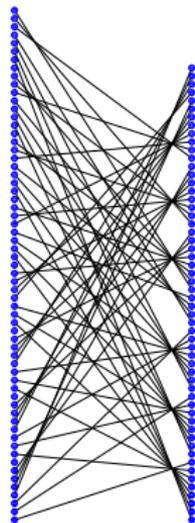

# DES: Key Scheduler

# DES: Feistel Network

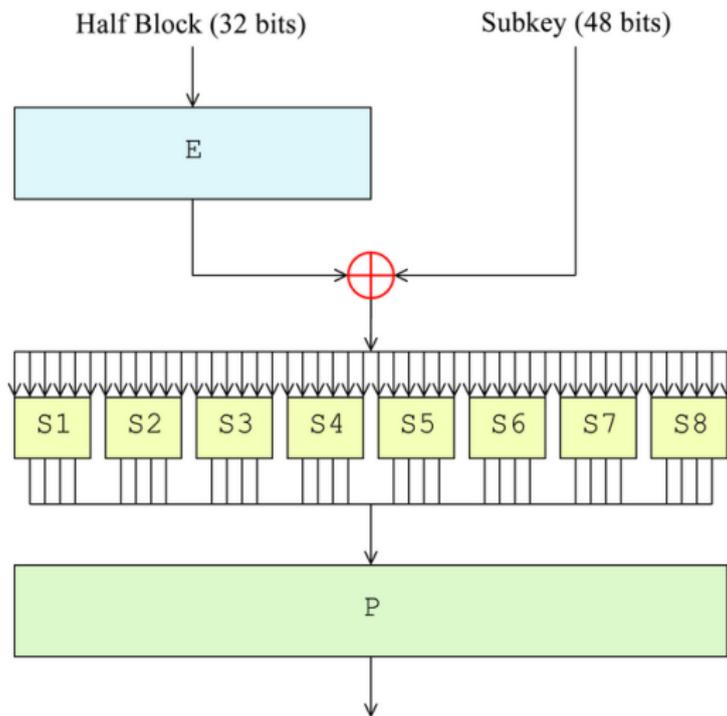

Source: Matt Crypto via: Wikipedia

- ▶ 16 rounds total (16 invocations of the  $f$  function).
- ▶ Each of the subkeys from the key scheduler is used for one invocation of  $f$ .
- ▶ The current right half of the block is used as input for  $f$ .
- ▶ The output of  $f$  is XORed with the left half of the block.
- ▶  $f$  need not be invertible.
- ▶ If  $f$  is linear, this network is fully linear (in  $\mathbb{F}_2$ ).
- ▶ Last step does not exchange (so encrypted sides are “swapped”).
- ▶ Inverting (decrypting) only requires regenerating the same inputs for  $f$  (in reverse order). This is the encrypt process, but with subkeys reversed.

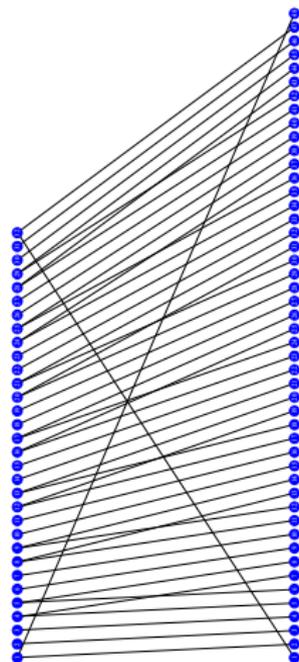

# DES: $f$ Function

# DES $f$ Function Expansion Goals

- ▶ Expand the input into eight 6-bit blocks.
- ▶ The middle 4 bits of each 6-bit block contain the complete message.
- ▶ Two adjacent blocks share two “message bits” ( $S_1$  and  $S_8$  are considered adjacent.)

- ▶ The non-linear component of  $f$ .
- ▶ Substitution and compression.
  - Each S-Box takes in 6 bits and outputs 4 bits.
  - Each S-Box acts by applying one of 4 permutations on the middle 4 bits.
  - The particular permutation used is selected depending on the first and last input bit.
- ▶ Selection of the S-Box is of paramount importance for the security of DES.
- ▶ S-Box design was made to be maximally resistant to differential cryptanalysis (an attack publicly known in the late 80s).
- ▶ S-Box design was not made resistant to linear cryptanalysis (an attack publicly known in 1992).

# Example S-Box

Input:  $x_1$   $y_1$   $y_2$   $y_3$   $y_4$   $x_2$

---

S1

|   | 0  | 1  | 2  | 3 | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |

|   |   |   |   |
|---|---|---|---|
| 1 | 0 | 1 | 1 |
|---|---|---|---|

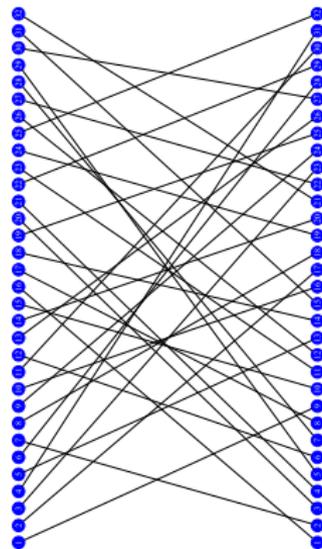

# DES: S-Box Design Goals

- S-1 No output bit of an S-box should be too close to a linear function of the input bits.
- S-2 If two inputs to an S-box differ in exactly one bit, the outputs must differ in at least two bits.
- S-3 If two inputs to an S-box differ in the two middle bits exactly, the outputs must differ in at least two bits.
- S-4 If two inputs to an S-box differ in their first two bits and are identical in their last two bits, the two outputs must not be the same.
- S-5 For any nonzero 6-bit difference between inputs no more than eight of the 32 pairs of inputs exhibiting this difference may result in the same output difference.
- S-6 Similar to (S-5), but with stronger restrictions in the case that there are three “active” S-Boxes.

# DES: $f$ Function Permutation

Source: SebDE via: Wikipedia

# DES: $f$ Function Permutation Design Goals

- P-1 The four output bits from each S-box at round  $i$  are distributed so that two of them affect “middle bits” of S-boxes at round  $i + 1$  (recall: the two middle bits of input to an S-box are not shared).
- P-2 The four output bits from each S-box affect six different S-boxes; no two affect the same S-box.
- P-3 For two S-boxes  $j, k$ , if an output bit from  $S_j$  affects a middle bit of  $S_k$ , then an output bit from  $S_k$  cannot affect a middle bit of  $S_j$ .

# DES: Cryptographic Foibles

- ▶  $y = e_k(m) \Leftrightarrow \bar{y} = e_{\bar{k}}(\bar{m})$ .
- ▶ If  $K_i = K_j$  for all  $i, j$ , then  $k$  is a weak key.
  - Encryption and decryption functions are the same.
  - For each weak key, there are  $2^{32}$  fixed points of  $e_k$ .
  - There are four weak keys.
- ▶ If  $e_k = d_{k'}$  then  $(k, k')$  are a semi-weak key pair.
  - There are six pairs of semi-weak keys.
  - For each of the semi-weak key pairs, there are  $2^{32}$  anti-fixed points  $e_k(x) = \bar{x}$ .

# DES: Theoretical Attack Landscape

- ▶ Brute force
  - $2^{55}$  operations, with 1 known plaintext.
  - Negligible block storage requirement.
- ▶ Differential Cryptanalysis
  - Chosen plaintext attack.
  - $2^{47}$  operations,  $2^{47}$  messages.
  - DES is optimized against Differential Cryptanalysis.
- ▶ Linear Cryptanalysis
  - Known plaintext attack.
  - Time / memory / success trade off
  - $2^{41}$  operations,  $2^{43}$  messages (85% chance of success)
  - $2^{50}$  operations,  $2^{38}$  messages (10% chance of success).
  - DES is not optimized against Linear Cryptanalysis.
- ▶ Only brute force is considered a viable attack in most settings.

# DES: Attack History

| Year      | Notes              | Cost                  | Runtime  |
|-----------|--------------------|-----------------------|----------|
| 1977      | Hellman design     | \$20M (est.)          | 1 day    |
| 1993      | Wiener design      | \$1M (est.)           | 7 hours  |
| 1997      | DESCHALL           | free (as in lemonade) | 96 days  |
| 1998      | EFF (“Deep Crack”) | \$250k                | 56 hours |
| 2006–2008 | COPACOBANA(s)      | \$10k                 | 7 days   |

- ▶ Two structural problems with using DES:
  - The block size is small.
  - The key size is small.
- ▶ The problem with key size can be addressed by iterating DES.
- ▶ DES is not a group, so iterated DES may be useful.
- ▶ By iterating DES (allowing distinct keys), there are provably at least  $10^{2499}$  distinct permutations obtainable.

- ▶ Iterating increases the number of key bits, which sounds good.
- ▶ Double encryption is not helpful:
  - A meet in the middle attack gives only a doubling of computational security!
  - Encrypt known plaintext with all possible keys.
  - Decrypt associated ciphertext with all possible keys. Look for matches.
  - Information theory tells us that we need two distinct ciphertext/plaintext pairs to uniquely identify the keys.
  - This attack requires on average  $2^{56.6}$  operations with  $2^{56}$  storage.
- ▶ Triple encryption is more helpful than the above suggests.

Input  $\rightarrow e_{k_1} \rightarrow d_{k_2} \rightarrow e_{k_3} \rightarrow$  Output

- ▶ Traditionally, one uses Encrypt-Decrypt-Encrypt (EDE) for encryption.
- ▶ Decrypt-Encrypt-Decrypt (DED) is then used for decryption.
  - This is not interesting for DES!
  - The only difference between encrypt and decrypt mode is the order in which subkeys are used.
- ▶ There are three common modes of Triple-DES.
  - 3-Key Triple-DES (All keys are distinct)
  - 2-Key Triple-DES ( $k_1 = k_3$ ,  $k_2$  is distinct)
  - 1-Key Triple-DES ( $k_1 = k_2 = k_3$ )

- ▶ Three-key triple-DES can be attacked in  $2^{112}$  operations; this attack requires  $2^{56}$  blocks of storage.
- ▶ Two-key triple-DES has a time-storage tradeoff attack:
  - $2^{56}$  operations,  $2^{56}$  storage required for attack,  $2^{56}$  chosen plaintexts.
  - $2^{80}$  operations,  $2^{40}$  storage required for attack,  $2^{40}$  chosen plaintexts.
- ▶ One-key triple-DES is equivalent to single-DES.
- ▶ “Internal chaining” weakens the cipher a great deal, generally to the level of single-DES.

## Subsection 2

### AES

# AES: The King is Dead, Long Live the King!

By 1997 it was clear that DES had some problems:

- ▶ The key length is too short for the modern computational environment.
- ▶ Triple-DES is very slow, particularly in software.
- ▶ The 64 bit block length leads to intrinsic limitations (birthday paradox problems).

# AES: The Selection Process

- ▶ September 12, 1997: NIST (née NBS) solicited submissions of ciphers to replace DES.
  - Required a block size of 128 bits.
  - Required a selectable key size of 128, 192, or 256 bits.
- ▶ 15 ciphers were submitted
- ▶ Conferences were scheduled to present cryptanalysis on the candidates.
  - AES1, August 1998
  - AES2, March 1999
  - AES3, April 2000.
- ▶ In August 1999, 5 finalists were selected by NIST.
- ▶ October 2, 2000 NIST announced that they had chosen Rijndael.

- ▶ 128 bit block size.
- ▶ 128, 192 or 256 bit key.
- ▶ An invocation of the Cipher consists of a few distinct components:
  1. Key Scheduler
  2. AddRoundKey
  3.  $N_r - 1$  Rounds
  4. FinalRound

# A Word on Finite Fields

- ▶ We are working in various finite fields.
- ▶ As a matter of practicality, we need to establish how to represent the field elements as binary strings.
- ▶ We'll express field elements as elements in  $\mathbb{F}_2[x]/\langle m(x) \rangle$  where  $m(x)$  is a degree 8 irreducible polynomial.
- ▶ Think: the set of polynomials of degree 7 or less, standard addition, reduce multiplication by the (irreducible) polynomial  $m(x)$ .
- ▶ We view bytes as elements of  $\mathbb{F}_{2^8}$ . (MSB:  $b_7$ . LSB:  $b_0$ )

$$b_7b_6b_5b_4b_3b_2b_1b_0 \iff \sum_{i=0}^7 b_i x^i$$

- ▶ For uniqueness of representation, we fix  $m(x) = x^8 + x^4 + x^3 + x + 1$ .

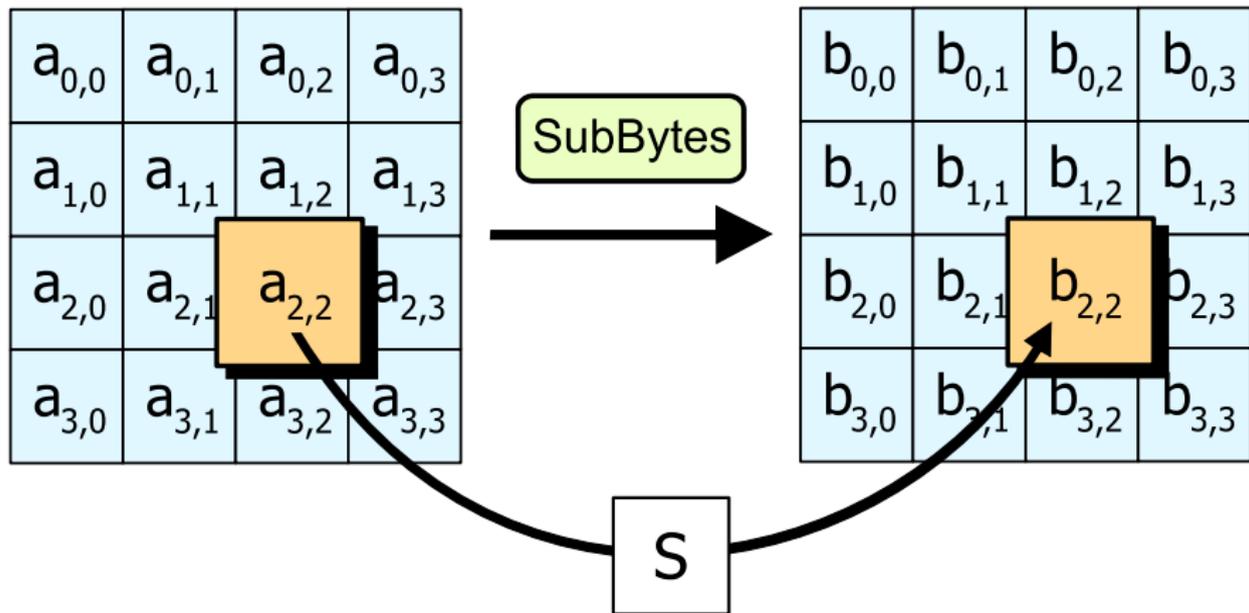

1. SubBytes
2. ShiftRows
3. MixColumns
4. AddRoundKey

The final round is the same, but without the MixColumns transform.

# AES: SubBytes Transform

Source: Matt Crypto via: Wikipedia

UNIVERSITY of CALIFORNIA • IRVINE

# AES: SubBytes Transform Specification

► The transform is  $S = f \circ g$  where:

1.  $g : \mathbb{F}_{2^8} \rightarrow \mathbb{F}_{2^8}$

$$g(a) = \begin{cases} a^{-1} & a \neq 0 \\ 0 & a = 0 \end{cases}$$

2.  $f : \mathbb{F}_2^8 \rightarrow \mathbb{F}_2^8$

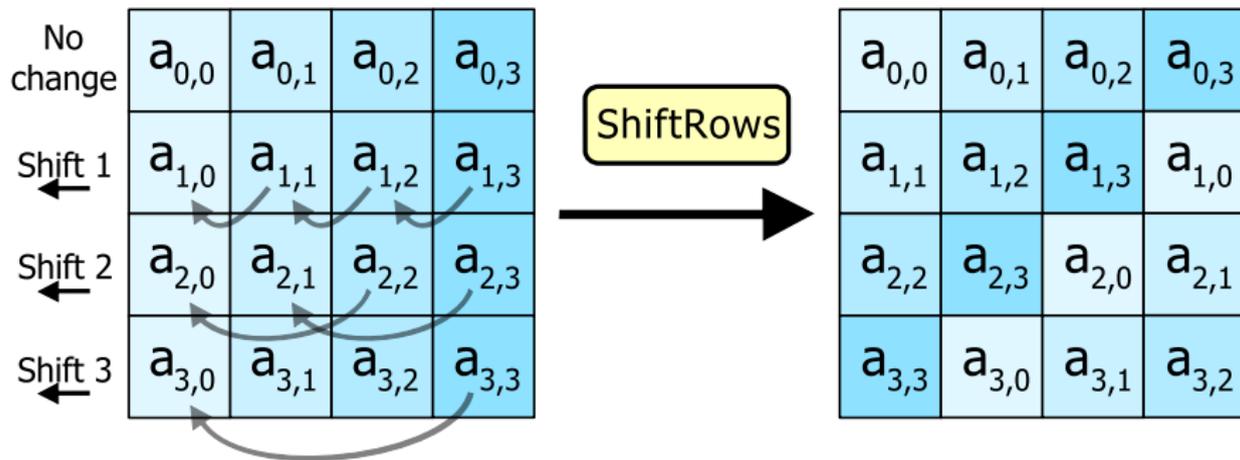

$$f \left( \begin{bmatrix} a_7 \\ a_6 \\ a_5 \\ a_4 \\ a_3 \\ a_2 \\ a_1 \\ a_0 \end{bmatrix} \right) = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \end{bmatrix} \times \begin{bmatrix} a_7 \\ a_6 \\ a_5 \\ a_4 \\ a_3 \\ a_2 \\ a_1 \\ a_0 \end{bmatrix} \oplus \begin{bmatrix} 0 \\ 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 1 \\ 1 \end{bmatrix}$$

- ▶ Every byte has exactly the same substitution.
- ▶ This substitution is not key dependent.
- ▶ The inverse operation is non-linear.
- ▶ The affine transformation was selected so that the algebraic expression of  $S$  in  $\mathbb{F}_{2^8}$  is complex.
- ▶ The affine transformation was selected so that there are no fixed or anti-fixed points.
- ▶ Both operations are clearly invertible;  $S^{-1} = g^{-1} \circ f^{-1}$ .

# AES: ShiftRows Transform

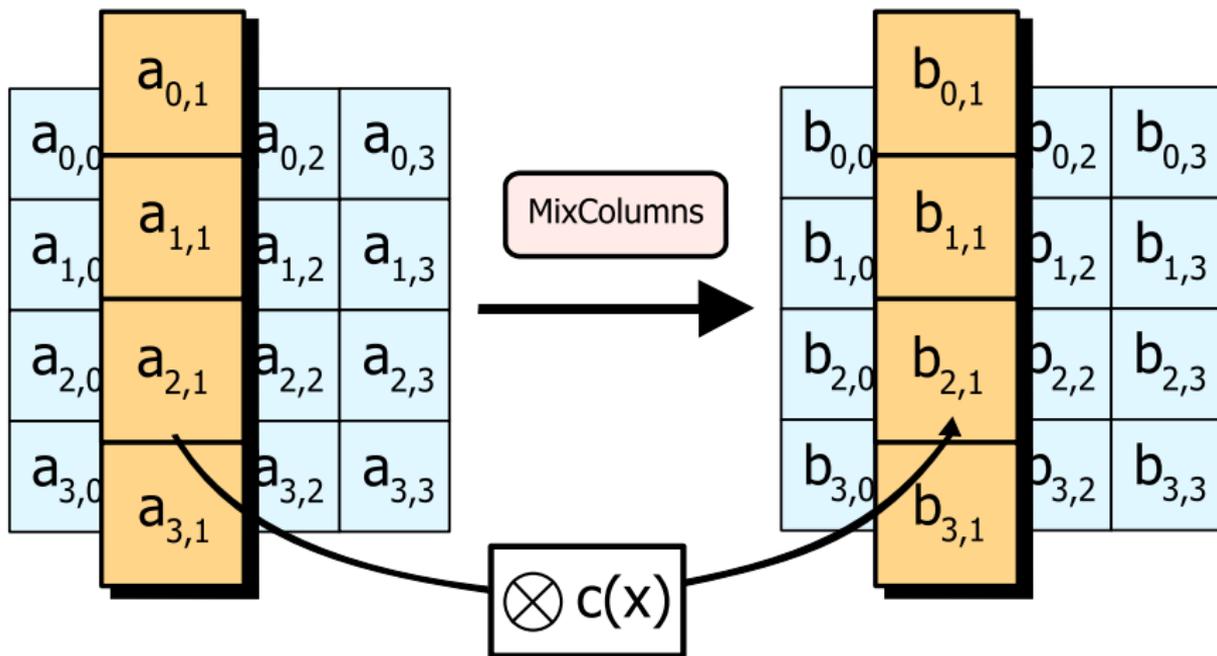

Source: Matt Crypto via: Wikipedia

- ▶ Cyclically shifts left the rows by different fixed amounts.
- ▶ Provides mixing of columns (diffusion).
- ▶ This is not key dependent.
- ▶ This helps protect against truncated differential and saturation attacks.
- ▶ The inverse operation just shifts the same amount in the opposite direction.

# AES: MixColumns Transform

Source: Matt Crypto via: Wikipedia

UNIVERSITY of CALIFORNIA • IRVINE

# AES: MixColumns Transform Specification

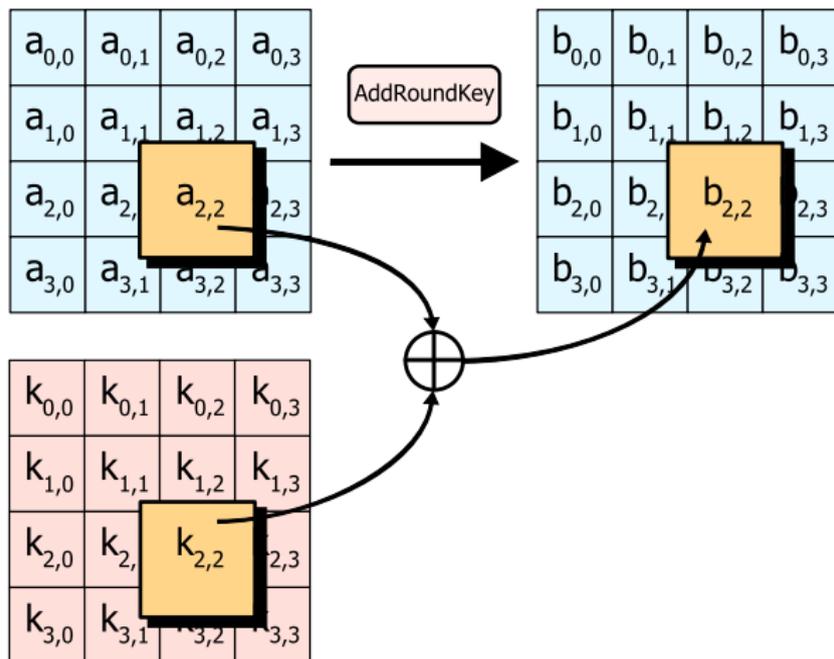

- ▶ Each column is viewed as the coefficients of a polynomial (of degree less than 4).
- ▶ The row number of the column is the power of  $x$ .
- ▶ This polynomial is multiplied by the fixed polynomial  $c(x) = 03x^3 + 01x^2 + 01x + 02$  and then reduced mod  $x^4 + 1$ .

- ▶ This is linear over  $\mathbb{F}_2$ .
- ▶ This contributes to diffusion.
- ▶  $c(x)$  is coprime with  $x^4 + 1$ , so it has an inverse:  
 $0Bx^3 + 0Dx^2 + 09x + 0E$
- ▶ This is not key dependent.

# AES: AddRoundKey Transform

Source: Matt Crypto via: Wikipedia

# AES: AddRoundKey Transform Notes

- ▶ This combines the round key with the data block through XOR.
- ▶ This is key dependent.
- ▶ This transform is self-inverting.

# AES: Number of Rounds

|        | Key size |     |     |
|--------|----------|-----|-----|
|        | 128      | 192 | 256 |
| Rounds | 10       | 12  | 14  |

- ▶ Full diffusion is provided after 2 rounds.
- ▶ Best known attacks at time of design stopped working starting at 6 rounds.
- ▶ Inserted “safety margin” of one full diffusion step at start and end of cipher, gives the 10 round value.
- ▶ More rounds are used for longer keys because the number of rounds makes various “short cut” attacks harder (and they should be as hard as guessing the longer key).
- ▶ Longer keys give an attacker more power for known- and related-key attacks.

# AES: Key Scheduler

- ▶ Expands the key from  $N_k$  32-bit words to  $N_r + 1$  round keys, each of which is 1 block (128 bits) long.
- ▶ First copies the provided key into the expanded key array.
- ▶ For later words, the  $i$ th word is the word one key length prior (the  $(i - N_k)$ th word) XORed with:
  - For words that are at a multiple of  $N_k$ , a processed version of the  $(i - 1)$ th word:
    1. Circularly rotated left one byte.
    2.  $S$  is applied to all bytes in the word.
    3. The first byte of the word is XORed with  $(\theta 2)^{i/N_k - 1}$ .
  - When  $N_k = 8$ , if  $i \equiv 4 \pmod{8}$ , the prior word after  $S$  has been applied to each byte.
  - Otherwise the prior word.

- ▶ AES (with 256 bit keys) is the only non-classified block cipher that is approved to protect Top Secret information.
- ▶ AES was designed to perform well against all known attacks at the time, and had a “safety margin” to help with unknown attacks.
- ▶ In 2009, a related key attack was found on the full 192 and 256 key length AES with work factor requiring  $2^{119}$  computations and plaintext / ciphertext pairs.
- ▶ In 2011, there was a full key recovery attack found which reduces security by at most 1.25 bits requiring  $2^{80}$  ciphertext / plaintext pairs.

## Subsection 3

### DES/AES Conclusion

- ▶ DES has been attacked for nearly 40 years.
- ▶ Several serious attacks have been found, through they are largely impractical.
- ▶ The most practical attack is simple brute force, which is practical.
- ▶ (Three-Key) Triple-DES addresses the brute force attack, but is very slow.
- ▶ Some birthday paradox related problems with the block size remain.

- ▶ AES has been attacked for 14 years.
- ▶ No serious attacks have been found, though there are hints that some serious reduction in strength may be possible.
- ▶ The most practical attack is simple brute force, which is not practical.
- ▶ Birthday attacks are largely addressed by the large 128-bit block size.

- ▶ The principal font is Evert Bloemsma's 2004 humanist san-serif font Legato. This font is designed to be exquisitely readable, and is a significant departure from the highly geometric forms that dominate most san-serif fonts. Legato was Evert Bloemsma's final font prior to his untimely death at the age of 46.
- ▶ Math symbols are typeset using the MathTime Professional II (MTPro2) fonts, a font package released in 2006 by the great mathematical expositor Michael Spivak.
- ▶ The URLs are typeset in Luc(as) de Groot's 2005 Consolas, a monospace font with excellent readability.
